#### 1 Wave diffraction from multiple truncated cylinders of arbitrary cross sections

2 Abstract: Many marine structures are supported by piles or caissons which, from a mathematical point of view, can be assimilated to an array of truncated cylinders of arbitrary cross sections. The 3 4 focus of this paper is such an array subjected to harmonic waves of small steepness. We develop 5 an analytic method based on linear potential flow theory to solve the diffraction problem and evaluate the excitation forces and moments acting on each cylinder. The water domain is divided 6 7 into the interior regions below each cylinder and an exterior region extending to infinity in the 8 horizontal plane. A series of eigen-functions are applied to express the velocity potential in each 9 region. The Fourier series method combined with the eigen-function expansion matching method 10 is used to satisfy the wetted surface body conditions and continuity conditions between adjacent 11 regions. The analytic model is validated by comparing its results with numerical modelling results 12 and published data. It is then applied to two truncated cylinders with caisson cross sections, and results are given for the excitation forces and moments on each cylinder for different values of 13 14 incident wave direction and spacing between the cylinders, and for different configurations.

16 Keywords: Wave diffraction; Wave excitation force; Wave-structure interaction; Truncated

17 cylinders; Potential flow; Analytical model

## 18 1. Introduction

There are many offshore structures that are composed of an array of cylinders, e.g., marine drilling platforms, floating airports, bridge pylons, offshore wind farms and wave farms [1]. For this reason the study of wave diffraction by multiple cylinders has sparked tremendous interest from engineers and researchers. When the cylinders in the array are far away from one another, the hydrodynamic interaction between them may be expected to be negligible; in such circumstances, the wave forces acting on each cylinder in the array are similar to those acting on an isolated cylinder.

26 Wave diffraction by a single cylinder with circular cross section has been widely investigated. 27 As early as 1971, Garrett [2] expanded an incident plane wave using Bessel functions and 28 conducted an analytic study on the scattering of waves by a circular dock, in which a series of 29 eigen-functions were applied to express the velocity potential and calculate wave forces. Black, 30 Mei and Bray [3] applied Haskind's theorem to evaluate the wave forces acting on a fixed vertical 31 truncated circular cylinder, which can be either partially immersed in the free surface or resting on 32 the seabed with its height completely submerged, with only far-field properties. The vertical wave force acting on the floating truncated cylinder was seen to approach the additional hydrostatic 33 34 force when the wave number tended to zero due to the free surface elevation, whereas the vertical force acting on the bottom-mounted cylinder became negligible as the wave number tended to 35 zero, for the cylinder had a vanishing water plane area. Wave diffraction from a circular cylinder 36 37 in other situations, e.g., located over a cylindrical barrier, floating in water of infinite depth, 38 located in front of a vertical wall, horizontal and submerged, were extensively investigated [4-15] 39 and brief reviews of the diffraction problems can also be found in our previous work [11, 12, 16].

In addition to the case of a cylinder of circular cross section, wave diffraction from a cylinder
of elliptic cross section has also attracted some attention. The exact analytic solution of wave
diffraction by a bottom-mounted, surface-piercing elliptic cylinder was first presented by Chen

and Mei [17]. In their study, the governing Laplace equation was expressed in elliptic cylindrical 1 2 coordinates; therefore, the fluid velocity potential was written in terms of infinite series of 3 Mathieu functions. This complete solution was considered too complex and costly for engineering applications[18]. To reduce the time required by the complete solution, Williams [18] presented 4 5 two approximate solutions for the diffraction problem and the calculation of the wave excitation 6 forces and moments on the surface-piercing elliptic cylinder. For a stationary cylinder of elliptic 7 shape, partially immersed, the hydrodynamic loading was analytically investigated by Chen and 8 Mei [19] based on linearized shallow water wave theory and adopting a depth-averaged velocity 9 potential, i.e., the velocity potentials in each region of the fluid domain were bidimensional, 10 without consideration of the vertical coordinate in the matching procedure (2DH). The 11 shallow-water theory was also employed by Williams [20] to study diffraction from a stationary 12 elliptic breakwater either partially immersed or totally submerged and resting on the sea-bed. Later, 13 these problems were re-investigated without the shallow-water restriction [21]; therefore, in addition to the angular coordinates, the vertical coordinate was retained in the analysis. The 14 15 theoretical solution of the interaction of linearized waves with a submerged horizontal disk of elliptic cross section can be found in Zhang and Williams [22]. 16

17 As regards cylinders with other cross-sections, a cosine-type cross-section was investigated 18 by Mansour, Williams and Wang [23], who presented a leading order analytic solution for a uniform, bottom-mounted, surface-piercing cylinder based on a perturbation theory, in terms of 19 the amplitude of the perturbation from a circular cross-section. Their analytic results were found to 20 21 be in good agreement with numerical results only for small values of the perturbation amplitude. 22 More recently, the linear wave diffraction by a vertical, uniform, surface piercing cylinder with an 23 arbitrary smooth cross-section was analytically solved by Liu, Guo and Li [24], Liu, Guo, Fang, Li, Hu and Liu [25]. The Fourier series method combined with the Galerkin method were used to 24 25 satisfy the wetted surface body conditions and continuity conditions between adjacent subdomains. Alternatively, Dişibűyűk, Korobkin and Yilmaz [26] solved wave diffraction from a uniform 26 27 vertical cylinder of arbitrary cross section by using an asymptotic approach, in which a fifth-order 28 asymptotic expansion of the velocity potential was substituted in the boundary condition. The 29 agreement between their theoretical predictions of the hydrodynamic forces and wave run-up and 30 those from Liu, Guo and Li [24] was shown to be fairly good.

For the majority of offshore structures that can be assimilated to an array of cylinders of arbitrary cross-sections, in practice, the spacing between the cylinders is typically not large enough for hydrodynamic interactions to be ignored; it follows that the wave excitation forces and moments acting on each cylinder are strongly affected by the waves diffracted from the others [27].

To analyse the hydrodynamic interaction occurring between multiple circular cylinders, 36 37 Kagemoto and Yue [28], Alliney [29] developed an interaction theory, which can be used to 38 predict wave exciting forces given only the diffraction characteristics of individual members. This 39 theory was also extended by Yilmaz and Incecik [30], Yilmaz [31] and Siddorn and Eatock Taylor 40 [32] to solve the problems of wave diffraction and radiation from an array of truncated vertical 41 circular cylinders. Linton and Evans [33] applied a direct method to wave diffraction problem of 42 multiple circular uniform cylinders and obtained new formulae for the wave excitation forces and 43 free-surface elevation close to a particular cylinder. Recently, Zheng and Zhang [34] presented a theoretical study on a hybrid wave energy converter, in which an analytic model was proposed to 44

solve the problems of wave diffraction and radiation from a hollow cylinder and a surrounding
array of solid cylinders. Analytic solutions of the hydrodynamic problems from a hybrid wave
farm consisting of an array of truncated cylinders with and without moonpools were derived as
well [35]. Other studies regarding wave diffraction of circular cylinders can be found in the review
presented by Eatock Taylor [36].

6 With regard to an array of elliptic uniform cylinders, Chatjigeorgiou and Mavrakos [37] 7 presented a semi-analytic model for the hydrodynamic diffraction. In their model, the Mathieu function addition theorem was adopted and properly extended so that it can be expressed in terms 8 9 of the even and odd periodic and radial Mathieu functions. Later, Chatjigeorgiou [38] provided an 10 analytic solution of hydrodynamic interactions between elliptic and circular uniform cylinders, in 11 which the circular cylinders were considered as different geometries rather than special cases of 12 elliptic cylinders with zero elliptic eccentricity. The theoretical model is more comprehensive, 13 requiring the implementation of both Mathieu and Bessel functions; in exchange, this approach allows for efficient and accurate computations. Chatjigeorgiou [39] extended the research work by 14 15 Chatjigeorgiou and Mavrakos [37] to multiple elliptic truncated cylinders. Chen and Lee [40] solved wave scattering from an array of four identical elliptical cylinders in a semi-analytical 16 17 manner. Both physical (near-trapped mode) and mathematical (fictitious frequency) resonances 18 were observed in their study. More recently, Zheng, Zhang, Liu and Iglesias [41] presented a semi-analytic model to solve the problem of wave radiation from cylinders with arbitrary cross 19 20 sections oscillating independently in the absence of an incident wave.

To the authors' best knowledge, there has been no analytic research work reported on wave scattering from an array of cylinders with arbitrary cross sections – a relevant problem in Ocean Engineering, and the subject of this paper. More specifically, we focus on wave diffraction from multiple stationary truncated cylinders partially immersed in the free surface, and propose an analytic model based on linear potential flow theory to solve the diffraction problem and evaluate the excitation forces and moments acting on each cylinder.

# 27 2. Mathematical model

28 The problem geometry is illustrated in Fig. 1. An array of N ( $N \ge 2$ ) vertical cylinders with arbitrary cross sections are partially immersed in water of finite depth h. The draft of cylinder n29  $(n=1,2,\ldots,N)$  is denoted as  $d_n$ . To describe the problem clearly, as shown in Fig. 1a, a Cartesian 30 31 coordinate system Oxyz is defined with the plane of Oxy coinciding with the still water level 32 (SWL) and the  $O_z$  pointing upwards. The multiple cylinders are subjected to a train of regular gravity waves of amplitude A and angular frequency  $\omega$  incoming at angle  $\beta$  to the positive 33 34 x-direction. The amplitude A is assumed to be small compared to the wavelength; in other words, 35 wave steepness is assumed to be small. Apart from the Oxyz system, N cylindrical coordinates are employed with the origins set inside the cross section of each cylinder at SWL. The cylindrical 36 coordinate corresponding to cylinder *n* is denoted as  $O_n r_n \theta_n z$  with the origin  $O_n$ , located at  $(x_n, y_n, 0)$ 37 38 in the Oxyz system. A point  $(x_n, y_n, z_n)$  in the Oxyz system is used as the reference point to calculate 39 the wave excitation moments acting on cylinder n. The fluid is divided into N+1 regions (Fig. 1b): 40 the first N regions are the interior regions below each cylinder; Region N+1 denotes the exterior 41 region, extending to infinity in the horizontal plane.

3 The shape of the cross section of cylinder *n* can be described in its own cylindrical coordinate 4 system  $O_n r_n \theta_n z$  as  $r_n = R_n(\theta_n)$ , which represents the radius of any point at the edge of cross section at  $\theta_n$ . In order to describe the unit normal vector at the side surface of cylinder n,  $S_n$  function is 5 6 introduced as:

$$S_n(r_n, \theta_n) = r_n - R_n(\theta_n), \qquad (1)$$

8 in which  $S_n=0$  represents the cross section of cylinder n as well, and the unit normal vector pointing into the water at the side surface in the  $O_n r_n \theta_n z$  system and the Oxyz system can be 9 10 written as Eqs. (2a) and (2b), respectively[16, 24, 41]:

11  
$$\vec{n} = \frac{1}{\sqrt{1 + \left(\frac{1}{r_n}\frac{\partial S_n}{\partial \theta_n}\right)^2}} \left(\vec{e}_{r,n} + \frac{1}{r_n}\frac{\partial S_n}{\partial \theta_n}\vec{e}_{\theta,n} + 0\vec{e}_z\right), \quad (2a)$$

12 
$$\vec{n} = \frac{1}{\sqrt{1 + \left(\frac{1}{r_n}\frac{\partial S_n}{\partial \theta_n}\right)^2}} \left( \left(\cos \theta_n - \frac{1}{r_n}\frac{\partial S_n}{\partial \theta_n}\sin \theta_n\right) \vec{i} + \left(\sin \theta_n + \frac{1}{r_n}\frac{\partial S_n}{\partial \theta_n}\cos \theta_n\right) \vec{j} + 0\vec{k} \right),$$

13

where  $(\vec{e}_{r,n}, \vec{e}_{\theta,n}, \vec{e}_z)$  are the unit basis vectors in the  $O_n r_n \theta_n z$  system, and  $(\vec{i}, \vec{j}, \vec{k})$  are the unit 14 15 basis vectors in the Oxyz system.

16 Assuming the fluid to be incompressible and inviscid, the irrotational fluid motion excited by 17 regular waves with small amplitude might be described by using linear flow potential theory and the velocity potential can be written as  $\varphi(x,y,z,t) = \operatorname{Re}[\Phi(x,y,z)e^{-i\omega t}]$ , where t is the time, i is the 18 19 imaginary unit,  $\Phi$  is a complex spatial velocity potential. It follows that both  $\varphi$  and  $\Phi$  satisfy the 20 Laplace equation everywhere in the fluid domain.

21 In the frame of the linear flow theory, the spatial velocity potential  $\Phi$  can be separated into 22 contributions from the incident wave field and the diffracted field as:

23

$$\boldsymbol{\Phi} = \boldsymbol{\Phi}_{\mathrm{I}} + \boldsymbol{\Phi}_{\mathrm{D}} \,, \tag{3}$$

(2b)

24 where  $\Phi_{\rm I}$  and  $\Phi_{\rm D}$  represent the incident wave spatial potential and the diffracted one, respectively. 25 Both of them satisfy the Laplace equation.

26 Generally, the velocity spatial potential for the undisturbed incident waves is well known and

7

1  $\Phi_{\rm I}$  in the  $O_n r_n \theta_{nz}$  system can be written as [34, 35]:

$$\boldsymbol{\Phi}_{\mathrm{I}} = -\frac{\mathrm{i}gA}{\omega} \frac{\mathrm{cosh}\left[k_0\left(z+h\right)\right]}{\mathrm{cosh}\left(k_0h\right)} \mathrm{e}^{\mathrm{i}k_0\left(x_n\cos\beta+y_n\sin\beta\right)} \sum_{m=-\infty}^{\infty} \mathrm{i}^m \mathrm{e}^{-\mathrm{i}m\beta} J_m\left(k_0r_n\right) \mathrm{e}^{\mathrm{i}m\theta_n} , \qquad (4)$$

3 where  $k_0$  is the wave number satisfying the dispersion relation  $\omega^2 = gk_0 \tanh(k_0 h)$ , in which g is the 4 gravity acceleration;  $J_m$  is the Bessel function of order m.

- 5 The boundary conditions for  $\Phi_{\rm D}$  can be written as follows:
- 6 1) The linear free surface condition:

2

7

9

11

12

25

$$\frac{\partial \Phi_{\rm D}}{\partial z} - \frac{\omega^2}{g} \Phi_{\rm D} = 0, \qquad z = 0 \quad \text{and} \quad r_n \ge R_n \tag{5}$$

8 2) The non-penetrating condition on the seabed:

$$\frac{\partial \Phi_{\rm D}}{\partial z} = 0, \qquad z = -h \tag{6}$$

10 3) The surface condition at the wetted surface of each cylinder:

$$\frac{\partial \Phi_{\rm D}}{\partial z} = -\frac{\partial \Phi_{\rm I}}{\partial z}, \qquad z = -d_n \quad \text{and} \quad 0 \le r_n \le R_n \tag{7}$$

$$\frac{\partial \Phi_{\rm D}}{\partial n} = -\frac{\partial \Phi_{\rm I}}{\partial n}, \quad -d_n \le z \le 0 \quad \text{and} \quad r_n = R_n \tag{8}$$

13 4) The radiation condition at infinity:

14 
$$\sqrt{k_0 r_n} \left( \frac{\partial \Phi_{\rm D}}{\partial r_n} - ik_0 \Phi_{\rm D} \right) = 0, \quad r_n \to \infty$$
 (9)

## 15 3 Solution to diffracted potentials

16 The diffracted spatial potential in Region *n* is denoted as  $\Phi_{D,n}$ . The method of separation of 17 variables is applied in each region in order to obtain expressions for the unknown diffracted 18 potentials.

# 19 3.1 Diffracted spatial potentials in different regions

20 1) Region 
$$n$$
 ( $n=1,2,...,N$ )

21 The diffracted spatial potential in Region *n* can be written in the  $O_n r_n \theta_n z$  system as

22 
$$\Phi_{\mathrm{D},n}(r_{n},\theta_{n},z) = \Phi_{\mathrm{D},n,\mathrm{p}} + \sum_{m=-\infty}^{\infty} \left[ A_{m,0}^{\mathrm{D},n}(r_{n})^{|m|} + \sum_{l=1}^{\infty} A_{m,l}^{\mathrm{D},n} I_{m}(\beta_{n,l}r_{n}) \cos\left[\beta_{n,l}(z+h)\right] \right] \mathrm{e}^{\mathrm{i}m\theta_{n}} , (10)$$

where  $A_{m,l}^{D,n}$  are unknown coefficients to be solved in Section 3.2;  $I_m$  is the modified Bessel function of first kind and order *m*;  $\beta_{n,l}$  is the eigenvalue which is given by

$$\beta_{n,l} = \frac{l\pi}{h - d_n}, \quad l = 0, 1, 2, 3, \dots,$$
(11)

26  $\Phi_{D,n,p}$  is a particular solution,  $\Phi_{D,n,p} = -\Phi_{I}$ .

1 2) Region *N*+1

In Region *N*+1, i.e., the exterior domain, the diffracted spatial potential can be decomposed
into the contributions from the waves diffracted from the *N* cylinders:

$$\Phi_{\rm D,N+1} = \sum_{n=1}^{N} \Phi_n^{\rm D,e} , \qquad (12)$$

5 in which  $\Phi_n^{D,e}$  represents the diffracted potential corresponding to the waves travelling outwards 6 from cylinder *n* and can be written in terms of eigen-function expansion in the  $O_n r_n \theta_n z$  system as:

$$\mathcal{P}_{n}^{\mathrm{D},\mathrm{e}}(r_{n},\theta_{n},z) = \sum_{m=-\infty}^{\infty} \left[ B_{m,0}^{\mathrm{D},n} H_{m}(k_{0}r_{n}) \frac{Z_{0}(z)}{Z_{0}(0)} + \sum_{l=1}^{\infty} B_{m,l}^{\mathrm{D},n} K_{m}(k_{l}r_{n}) \frac{Z_{l}(z)}{Z_{l}(0)} \right] \mathrm{e}^{\mathrm{i}m\theta_{n}}$$
(13)

8 where

4

9 
$$Z_0(z) = N_0^{-1/2} \cosh[k_0(z+h)]; \quad Z_1(z) = N_1^{-1/2} \cos[k_1(z+h)];$$
 (14)

10 
$$N_0 = \frac{1}{2} \left[ 1 + \frac{\sinh(2k_0h)}{2k_0h} \right]; \quad N_l = \frac{1}{2} \left[ 1 + \frac{\sin(2k_lh)}{2k_lh} \right]; \quad (15)$$

11  $B_{m,l}^{D,n}$  are the unknown coefficients to be solved in Section 3.2;  $H_m$  is the Hankel function of 12 first kind of order *m*;  $K_m$  is the modified Bessel function of second kind of order *m*;  $k_l$  is the 13 eigenvalue which is given by

$$\omega^2 = -k_l g \tan(k_l h), \qquad l=1,2,3,...$$
 (16)

15 With the employment of Graf's addition theorem for Bessel functions [11, 12, 28, 32, 34, 42], 16  $\Phi_j^{D,e}$  can be expressed in different cylindrical coordinate systems, and when  $r_n \leq R_{jn}$ , Eq. (12) can 17 be rewritten in the  $O_n r_n \theta_{nz}$  system as:

$$\begin{split} \mathcal{\Phi}_{\mathrm{D},N+1}(r_{n},\theta_{n},z) &= \sum_{m=-\infty}^{\infty} \left[ B_{m,0}^{\mathrm{D},n}H_{m}(k_{0}r_{n})\frac{Z_{0}(z)}{Z_{0}(0)} + \sum_{l=1}^{\infty}B_{m,l}^{\mathrm{D},n}K_{m}(k_{l}r_{n})\frac{Z_{l}(z)}{Z_{l}(0)} \right] \mathrm{e}^{\mathrm{i}m\theta_{n}} \\ &+ \sum_{\substack{j=1\\j\neq n}}^{N}\sum_{m=-\infty}^{\infty} \left\{ B_{m,0}^{\mathrm{D},j}\frac{Z_{0}(z)}{Z_{0}(0)}\sum_{m'=-\infty}^{\infty}(-1)^{m'}H_{m-m'}(k_{0}R_{jn})J_{m'}(k_{0}r_{n})\mathrm{e}^{\mathrm{i}(m\alpha_{jn}-m'\alpha_{nj})}\mathrm{e}^{\mathrm{i}m'\theta_{n}} \right. .(17) \\ &+ \sum_{l=1}^{\infty}B_{m,l}^{\mathrm{D},j}\frac{Z_{l}(z)}{Z_{l}(0)}\sum_{m'=-\infty}^{\infty}K_{m-m'}(k_{l}R_{jn})I_{m'}(k_{l}r_{n})\mathrm{e}^{\mathrm{i}(m\alpha_{jn}-m'\alpha_{nj})}\mathrm{e}^{\mathrm{i}m'\theta_{n}} \bigg\} \end{split}$$

#### 18

23

# 19 3.2 Method of computation for unknown coefficients

The unknown coefficients in Eqs. (10), (13) and (17) can be determined by using the conditions of continuity of pressure and mass flux at  $r_n=R_n$  (n=1,2,...,N):

22 1) Continuity of pressure at the boundary  $S_n=0$ :

$$\Phi_{\mathrm{D},N+1}\Big|_{S_n=0} = \Phi_{\mathrm{D},n}\Big|_{S_n=0}, \qquad -h < z < -d_n.$$
(18)

24 2) Continuity of mass flux at the boundary  $S_n=0$ :

$$\frac{\partial \Phi_{\mathrm{D},N+1}(r_{n},\theta_{n},z)}{\partial n}\Big|_{S_{n}=0} = \begin{cases} -\frac{\partial \Phi_{1}(r_{n},\theta_{n},z)}{\partial n}\Big|_{S_{n}=0}, & -d_{n} < z < 0\\ \frac{\partial \Phi_{\mathrm{D},n}(r_{n},\theta_{n},z)}{\partial n}\Big|_{S_{n}=0}, & -h < z < -d_{n} \end{cases}$$
(19a)

which, with the employment of Eq. (2a), can be further expressed in the frame of the local cylindrical coordinate system  $O_n r_n \theta_{nZ}$  as

1

$$4 \qquad \left( r_n^2 \frac{\partial \boldsymbol{\Phi}_{\mathrm{D},N+1}}{\partial r_n} + \frac{\partial S_n}{\partial \theta_n} \frac{\partial \boldsymbol{\Phi}_{\mathrm{D},N+1}}{\partial \theta_n} \right) \Big|_{S_n=0} = \begin{cases} -\left( r_n^2 \frac{\partial \boldsymbol{\Phi}_{\mathrm{I}}}{\partial r_n} + \frac{\partial S_n}{\partial \theta_n} \frac{\partial \boldsymbol{\Phi}_{\mathrm{I}}}{\partial \theta_n} \right) \Big|_{S_n=0}, \quad -d_n < z < 0 \\ \left( r_n^2 \frac{\partial \boldsymbol{\Phi}_{\mathrm{D},n}}{\partial r_n} + \frac{\partial S_n}{\partial \theta_n} \frac{\partial \boldsymbol{\Phi}_{\mathrm{D},n}}{\partial \theta_n} \right) \Big|_{S_n=0}, \quad -h < z < -d_n \end{cases}$$
(19b)

5 After inserting the expressions of the wave diffracted spatial potential as given in Eqs. (10) 6 and (17) into Eqs. (18) and (19b), the terms with  $r_n$  and  $\partial S_n / \partial \theta_n$  at  $S_n=0$  are both found to be 7 dependent on  $\theta_n$ , and can be expanded into a Fourier series as follows [41]:

8 
$$J_m(k_0r_n)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,0,q}^{J,n} e^{iq\theta_n}; \left(r_n^2 k_0 J'_m(k_0r_n) + im J_m(k_0r_n) \frac{\partial S_n}{\partial \theta_n}\right)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,0,q}^{J',n} e^{iq\theta_n}$$
 (20a)

9 
$$H_m(k_0r_n)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,0,q}^{H,n} e^{iq\theta_n}; \left(r_n^2 k_0 H'_m(k_0r_n) + imH_m(k_0r_n)\frac{\partial S_n}{\partial \theta_n}\right)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,0,q}^{H',n} e^{iq\theta_n}$$
 (20b)

$$K_m(k_l r_n)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,l,q}^{K,n} e^{iq\theta_n} ; \left( r_n^2 k_l K_m'(k_l r_n) + im K_m(k_l r_n) \frac{\partial S_n}{\partial \theta_n} \right)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,l,q}^{K',n} e^{iq\theta_n}$$
(20c)

$$II \qquad I_m(k_l r_n)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,l,q}^{I,n} e^{iq\theta_n} ; \left( r_n^2 k_l I'_m(k_l r_n) + im I_m(k_l r_n) \frac{\partial S_n}{\partial \theta_n} \right)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,l,q}^{I',n} e^{iq\theta_n}$$
(20d)

$$I_{m}\left(\beta_{n,l}r_{n}\right)\Big|_{S_{n}=0} = \sum_{q=-\infty}^{\infty} \tilde{f}_{m,l,q}^{I,n} e^{iq\theta_{n}} \left(r_{n}^{2}\beta_{n,l}I_{m}'\left(\beta_{n,l}r_{n}\right) + imI_{m}\left(\beta_{n,l}r_{n}\right)\frac{\partial S_{n}}{\partial\theta_{n}}\right)\Big|_{S_{n}=0} = \sum_{q=-\infty}^{\infty} \tilde{f}_{m,l,q}^{I',n} e^{iq\theta_{n}}$$
(20e)

13 
$$(r_n)^{|m|}\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} f_{m,0,q}^{R,n} e^{iq\theta_n}; \left( |m|(r_n)^{|m|+1} + im(r_n)^{|m|} \frac{\partial S_n}{\partial \theta_n} \right)\Big|_{S_n=0} = \sum_{q=-\infty}^{\infty} \tilde{f}_{m,0,q}^{R,n} e^{iq\theta_n}$$
 (20f)

for n=1...N, where the Fourier coefficients on the right-hand side of Eqs. (20a)~(20f), represented by  $\Re_{n,q}$  for convenience, can be obtained from

16 
$$\Re_{n,q} = \frac{1}{2\pi} \int_{-\pi}^{\pi} \Psi_{n,q} \left( \theta_n \right) e^{-iq\theta_n} d\theta_n , \qquad (21)$$

<sup>17</sup> in which  $\Psi_{n,q}$  denotes the  $\theta_n$  dependent items as given at the left side of Eqs. (20a)~(20f).

18 The orthogonal properties of the functions  $\cos n\theta$ ,  $\sin n\theta$ , and  $Z_l(z)$  can also be used by 19 multiplying Eqs. (18) and (19) with  $e^{-i\tau\theta_n} \cos\left[\beta_{n,\varsigma}(z+h)\right]/(h-d_n)$  and  $e^{-i\tau\theta_n}Z_{\varsigma}/h$ , respectively, on both sides and integrating with respect to  $\theta$  and z, as follows:

$$\sum_{n=1}^{\pi} \left[ \int_{-h}^{-d_n} \Phi_{D,N+1}(r_n,\theta_n,z) \Big|_{S_n=0} \frac{\cos\left[\beta_{n,\varsigma}(z+h)\right]}{h-d_n} dz \right] e^{-i\tau\theta_n} d\theta_n$$

$$= \int_{-\pi}^{\pi} \left[ \int_{-h}^{-d_n} \Phi_{D,n}(r_n,\theta_n,z) \Big|_{S_n=0} \frac{\cos\left[\beta_{n,\varsigma}(z+h)\right]}{h-d_n} dz \right] e^{-i\tau\theta_n} d\theta_n$$
(22)

$$\int_{-\pi}^{\pi} \left[ \int_{-h}^{0} \frac{\partial \boldsymbol{\varPhi}_{\mathrm{D},N+1}(\boldsymbol{r}_{n},\boldsymbol{\theta}_{n},z)}{\partial n} \Big|_{\boldsymbol{s}_{n}=0} \frac{\boldsymbol{Z}_{\varsigma}(\boldsymbol{z})}{h} d\boldsymbol{z} \right] \mathrm{e}^{-\mathrm{i}\,\boldsymbol{\tau}\boldsymbol{\theta}_{n}} d\boldsymbol{\theta}_{n}$$

$$= \int_{-\pi}^{\pi} \left[ \int_{-h}^{-d_{n}} \frac{\partial \boldsymbol{\varPhi}_{\mathrm{D},n}(\boldsymbol{r}_{n},\boldsymbol{\theta}_{n},z)}{\partial n} \Big|_{\boldsymbol{s}_{n}=0} \frac{\boldsymbol{Z}_{\varsigma}(\boldsymbol{z})}{h} d\boldsymbol{z} - \int_{-d_{n}}^{0} \frac{\partial \boldsymbol{\varPhi}_{1}(\boldsymbol{r}_{n},\boldsymbol{\theta}_{n},z)}{\partial n} \Big|_{\boldsymbol{s}_{n}=0} \frac{\boldsymbol{Z}_{\varsigma}(\boldsymbol{z})}{h} d\boldsymbol{z} \right] \mathrm{e}^{-\mathrm{i}\,\boldsymbol{\tau}\boldsymbol{\theta}_{n}} d\boldsymbol{\theta}_{n}$$

$$(23)$$

in which  $\tau$  is an integer which varies from minus infinity to plus infinity, and  $\zeta$  is an integer varying from zero to plus infinity.

Substituting the expressions for the wave diffracted spatial potential in Eqs. (10) and (17), inserting the Fourier coefficients in Eqs. (20a)~(20f) into Eqs. (22) and (23), and making some rearrangements, we have

9  

$$-\sum_{m=-\infty}^{\infty} A_{m,\tau,\zeta}^{l,n} A_{m,\zeta}^{D,n} + \sum_{m=-\infty}^{\infty} \sum_{l=0}^{\infty} B_{m,l}^{D,n} L_{l,\zeta}^{(n)} A_{m,\tau,l}^{2,n} + \sum_{\substack{j=1\\j\neq n}}^{N} \sum_{m=-\infty}^{\infty} \sum_{l=0}^{\infty} B_{m,l}^{D,j} L_{l,\zeta}^{(n)} T_{m,\tau,l}^{n,j} , \qquad (24)$$

$$= \frac{igA}{\omega} L_{0,\zeta}^{(n)} e^{ik_0(x_n \cos\beta + y_n \sin\beta)} \sum_{m=-\infty}^{\infty} i^m e^{-im\beta} f_{m,0,\tau-m}^{J,n}$$

$$- \frac{h - d_n}{h} Z_{\zeta}(0) \sum_{m=-\infty}^{\infty} \sum_{l=0}^{\infty} A_{m,l}^{D,n} L_{\zeta,l}^{(n)} A_{m,\tau,l}^{3,n} + \sum_{m=-\infty}^{\infty} B_{m,\zeta}^{D,n} A_{m,\tau,\zeta}^{4,n} + \sum_{\substack{j=1\\j\neq n}}^{N} \sum_{m=-\infty}^{N} B_{m,\zeta}^{2,n} + \sum_{\substack{j$$

where

$$\Lambda_{m,\tau,\varsigma}^{l,n} = \begin{cases}

(26)

$$L_{l,\varsigma}^{(n)} = \frac{1}{h - d_n} \int_{-h}^{-d_n} \frac{Z_l(z) \cos\left[\beta_{n,\varsigma}(z+h)\right]}{Z_l(0)} dz$$

$$= \begin{cases} \frac{(-1)^{\varsigma} (h - d_n) k_0 \sinh\left[k_0 (h - d_n)\right]}{\left[(h - d_n)^2 k_0^2 + \varsigma^2 \pi^2\right] \cosh(k_0 h)} & l = 0; \varsigma = 0, 1, 2 \cdots \\ \frac{(-1)^{\varsigma} (h - d_n) k_l \sin\left[k_l (h - d_n)\right]}{\left[(h - d_n)^2 k_l^2 - \varsigma^2 \pi^2\right] \cos(k_l h)} & l = 1, 2, 3 \cdots; \varsigma = 0, 1, 2 \cdots \end{cases}$$
(27)

$$1 T_{m,\tau,l}^{n,j} = \begin{cases} \sum_{m'=-\infty}^{\infty} (-1)^{m'} H_{m-m'}(k_0 R_{jn}) f_{m',0,\tau-m'}^{J,n} e^{i(m\alpha_{jn}-m'\alpha_{nj})}, & l = 0\\ \sum_{m'=-\infty}^{\infty} K_{m-m'}(k_l R_{jn}) f_{m',l,\tau-m'}^{J,n} e^{i(m\alpha_{jn}-m'\alpha_{nj})}, & l = 1, 2, 3, \dots \end{cases}$$
(28)

$$2 \qquad \qquad A_{m,\tau,l}^{3,n} = \begin{cases} \tilde{f}_{m,0,\tau-m}^{R,n}, & l=0\\ \tilde{f}_{m,l,\tau-m}^{I',n}, & l=1,2,3,\dots \end{cases} \qquad A_{m,\tau,\varsigma}^{4,n} = \begin{cases} \frac{f_{m,0,\tau-m}^{H',n}}{Z_0(0)}, & \varsigma=0\\ \frac{f_{m,\zeta,\tau-m}^{K',n}}{Z_{\varsigma}(0)}, & \varsigma=1,2,3,\dots \end{cases}$$
(29)

$$T_{m,\tau,l}^{\prime n,j} = \begin{cases} \frac{1}{Z_0(0)} \sum_{m'=-\infty}^{\infty} (-1)^{m'} H_{m-m'} (k_0 R_{jn}) f_{m',0,\tau-m'}^{J',n} e^{i(m\alpha_{jn}-m'\alpha_{nj})}, & l = 0\\ \frac{1}{Z_l(0)} \sum_{m'=-\infty}^{\infty} K_{m-m'} (k_l R_{jn}) f_{m',l,\tau-m'}^{J',n} e^{i(m\alpha_{jn}-m'\alpha_{nj})}, & l = 1, 2, 3, \dots \end{cases}$$
(30)

We truncate (2*M*+1) terms (*m*=-*M*,...,0, ..., *M*) and (*L*+1) terms (*l*=0,1, ..., *L*) in Eqs. (10),
(13), (24) and (25) and take (τ=-*M*,...,0, ..., *M*) and (ζ=0,1, ..., *L*) in Eqs. (24) and (25) as well,
thus a 2*N*(2*M*+1)(*L*+1)-order complex linear equation matrix is obtained, which can be used to
calculate the same number of unknown coefficients A<sup>D,n</sup><sub>m,l</sub> and B<sup>D,n</sup><sub>m,l</sub>. In the following analytic
computations, *M*=15 and *L*=8 are taken so as to obtain accurate results.

# 9 4 Wave excitation forces and moments

10 The hydrodynamic pressure in the flow domain is given by the linearized Bernoulli equation, 11  $p=-\rho\partial \operatorname{Re}[(\Phi_{\mathrm{I}}+\Phi_{\mathrm{D}})e^{-i\omega t}]/\partial t = \rho \operatorname{Re}[i\omega(\Phi_{\mathrm{I}}+\Phi_{\mathrm{D}})e^{-i\omega t}]$ , where  $\rho$  represents the water density. Therefore, 12 the generalized excitation force on cylinder *n* in Mode *j* (*j*=1~6 represent surge, sway, heave, roll, 13 pitch and yaw, respectively) can be calculated from  $\operatorname{Re}\left[F_{\mathrm{e},n}^{(j)}e^{-i\omega t}\right]$ , where

14 
$$F_{e,n}^{(j)} = -i\omega\rho \int_{S_n} (\Phi_1 + \Phi_D) n_j ds, \qquad (31)$$

15 in which  $S_n$  is the wetted surface of cylinder n;  $n_1=n_x$ ,  $n_2=n_y$   $n_3=n_z$ ,  $n_4=-(z-z_n)n_y+(y-y_n)n_z$ , 16  $n_5=(z-z_n)n_x-(x-x_n)n_z$ ,  $n_6=-(y-y_n)n_x+(x-x_n)n_y$ ,  $\vec{n}=n_x\vec{i}+n_y\vec{j}+n_z\vec{k}$  is the unit normal vector directed 17 into the fluid domain at the cylinder surface, as given in Eq. (2b).

The analytic expressions for the diffracted potentials of the whole computational domain are
obtained in Section 3, so the wave excitation forces and moments can be calculated directly from
Eq. (31).

## 21 5 Model validation

Multiple caissons arise in many offshore projects, such as floating bridges [43] and mobile offshore bases [1]. In this section, the case of two caissons (Fig. 2) is used for validating the analytic model of wave diffraction from multiple truncated cylinders of arbitrary cross sections. Located in water with a depth of h=20 m, the two caissons have the same dimensions and a draft  $d_n=5$  m. They are deployed in parallel at a distance from each other e=20 m, and are subjected to regular waves propagating at an angle  $\beta=\pi/6$ .

Fig. 2. Top view of the two caissons, case study used for validation.

4 After solving wave diffraction problem from these caissons, the wave excitation forces and 5 moments obtained are then normalized as follows:

$$\overline{F}_{e,n}^{(j)} = \frac{\left|F_{e,n}^{(j)}\right|}{\rho g A h^{q}}, \qquad q = \begin{cases} 2, & j = 1, 2, 3\\ 3, & j = 4, 5, 6 \end{cases},$$
(32a)

7

6

<sup>8</sup> Hereinafter, 
$$k_0$$
 is denoted as k for simplicity, and the nondimensional wave frequency kh is used.

 $\varphi_{\mathrm{e},n}^{(j)} = \arg F_{\mathrm{e},n}^{(j)}.$ 

Figures 3 and 4 present a comparison of the present analytic results of wave excitation
forces/moments acting on the two caissons (see Fig.2) for different wave frequencies (0<*kh*<5.0)</li>
with the numerical results from BEM-based software, ANSYS-AQWA [44]. Figs. 3a and 3b show
the wave excitation forces acting on Caisson 1 in terms of dimensionless amplitude and phase
angle, respectively. The wave excitation forces acting on Caissons 1 and 2 are illustrated in Figs. 4a~4b and
Figs. 4c~4d, respectively.

(32b)

Fig. 3. Comparison of the present analytic results of wave excitation forces acting on the two caissons with the numerical results based on BEM for  $\beta = \pi/6$  and e/h = 1.0: (a)  $\overline{F}_{e,1}^{(n)}$ , n = 1,2,3; (b)  $\varphi_{e,1}^{(n)}$ , n = 1,2,3; (c)  $\overline{F}_{e,2}^{(n)}$ , n = 1,2,3; (d)  $\varphi_{e,1}^{(n)}$ , n = 1,2,3. [Lines: analytic results; symbols: numerical results].

6 7

8

9 10

Fig. 4. Comparison of the present analytic results of wave excitation moments acting on the two caissons with the numerical results based on BEM for  $\beta = \pi/6$  and e/h = 1.0: (a)  $\overline{F}_{e,1}^{(n)}$ , n=4,5,6; (b)  $\varphi_{e,1}^{(n)}$ , n=4,5,6. [Lines: analytic results; symbols: numerical results].

It is shown that the analytic results of the excitation forces and moments acting on each caisson in all modes, i.e., surge, sway, heave, roll, pitch and yaw, fully agree with the numerical results in terms of both dimensionless amplitude and phase angle. This excellent agreement validates the present analytic model.

In addition to the two caissons with a quasi-elliptical cross section, a square array of four identical elliptical cylinders studied analytically by Chen and Lee [40] is selected to validate the present analytic model. All cylinders are fixed on the seabed mounted upward to the free surface. The half lengths of the major and the minor axes of each elliptical cylinder are *h* and 0.5*h*, respectively. The incident wave direction is  $\beta$ =0. In the present computation,  $d_n$ = 0.98*h* (*n*=1, 2, 3, 4) was adopted to represent that the cylinders were bottom-mounted. As shown in Fig. 5, the present results of the surge wave excitation forces are in excellent agreement with those in [40].

3

4 5

Fig. 5. Comparison of the present analytic results of the surge wave excitation forces acting on each cylinder of an array of four identical elliptical cylinders with the published data [40] for  $\beta=0.$  [ $\overline{F}_{e,1}^{(0)}$  denotes the surge wave excitation force acting on the cylinder-1 when it is in isolation]

6 6 Results and discussion

In this section, the validated analytic model is applied to investigate the role of the incident
wave direction, spacing between caissons and configuration angle in the hydrodynamic forces and
moments acting on the two caissons depicted in Fig. 2.

## 10 6.1 Effect of incident wave angle

11 The two caissons suffering from incoming regular waves with five different incident wave 12 angles, i.e.,  $\beta = 0$ ,  $\pi/6$ ,  $\pi/4$ ,  $\pi/3$  and  $\pi/2$ , are tested. Figure 6 shows the variations of the excitation 13 forces acting on each caisson in surge, sway and heave modes with *kh* for different values of  $\beta$  and 14 e/h=1.0. Similarly, the results of the excitation moments in roll, pitch and yaw modes are 15 presented in Fig. 7.

16 Since both caissons have the same dimensions and are arranged in parallel symmetrically, the 17 results of the excitation forces and moments acting on them in any mode should be the same in 18 terms of amplitude when  $\beta = \pi/2$ . This is borne out by the results in Figs. 6 and 7.

For  $\beta = \pi/2$ , the surge excitation force, pitch and yaw excitation moments acting on the isolated induvidual caisson vanish. By contrast, when two caissons are deployed in proximity (Fig. 2), the surge excitation force, and the pitch and yaw excitation moments acting on each caisson may be non-zero due to the hydrodynamic interaction between the caissons. Note that for *kh*=3.6 and  $\beta = \pi/4$ ,  $\overline{F}_{e,1}^{(1)}$  and  $\overline{F}_{e,2}^{(1)}$  are 0.056 and 0.282, respectively, implying that, under certain circumstances, the wave excitation forces acting on the leeward caisson can be larger than those acting on the windward caisson.

When incident waves propagate along the x-axis, i.e.,  $\beta=0$ , due to the symmetrical property of the two caissons about the plane of y=0,  $\overline{F}_{e,n}^{(2)}$ ,  $\overline{F}_{e,n}^{(4)}$  and  $\overline{F}_{e,n}^{(6)}$  all vanish (Figs. 6c, 6d, 7a, 7b, 7e and 7f). For kh<3.5, the larger the  $\beta$ , the larger the  $\overline{F}_{e,1}^{(2)}$  and  $\overline{F}_{e,2}^{(2)}$ . This also applies to the effect of  $\beta$  on  $\overline{F}_{e,1}^{(4)}$  and  $\overline{F}_{e,2}^{(4)}$  for kh<3.5.

30  $\beta$  might play opposite roles on  $\overline{F}_{e,1}^{(3)}$  for different wave frequencies. For kh < 1.0, a larger  $\beta$ 31 results in a smaller  $\overline{F}_{e,1}^{(3)}$ . Whereas for 1.5< kh < 1.8, a larger  $\overline{F}_{e,1}^{(3)}$  is obtained for a larger  $\beta$ . For 32 2.0< kh < 5.0, at least one peak of  $\overline{F}_{e,1}^{(3)} - kh$  occurs for any  $\beta$  studied, except  $\beta = \pi/2$ . The kh corresponding to the peaks is rather dependent on β. As a comparison, althouth peaks also appear
 for \$\bar{F}\_{e,2}^{(3)}\$-kh at 2.0< kh<5.0\$, the kh values where peaks occur are rather independent of β.</li>
 When the caissons are subjected to oblique waves, i.e., \$\beta=\pi/6\$, \$\pi/4\$ and \$\pi/3\$, \$\bar{F}\_{e,1}^{(4)}\$ and \$\bar{F}\_{e,2}^{(4)}\$

3 When the caissons are subjected to oblique waves, i.e.,  $\beta = \pi/6$ ,  $\pi/4$  and  $\pi/3$ ,  $\overline{F}_{e,1}^{(4)}$  and  $\overline{F}_{e,2}^{(4)}$ 4 are found to vanish for certain wave conditions (Figs.7a and 7b). Such circumstances are welcome 5 from the standpoint of offshore structures' stability. It may be inferred that the larger the  $\beta$ , the 6 larger the *kh* where  $\overline{F}_{e,1}^{(4)}$  and  $\overline{F}_{e,2}^{(4)}$  vanish.

7 The effect of  $\beta$  on pitch moments is found to be similar to that on surge forces (Figs.7c and 8 7d). This may be partially due to the position of the rotational reference point, which is located at 9 SWL, implying that the arm of the surge force is generally larger than the arm of the heave force; 10 therefore, the pitch moment is dominated by the part of the surge force acting on the side walls.

11 Although  $\overline{F}_{e,1}^{(6)}(\overline{F}_{e,2}^{(6)})$  is excited for  $\beta = \pi/2$  due to hydrodynamic interaction between the 12 caissons, its value is rather small (Figs.7e and 7f).  $\overline{F}_{e,1}^{(6)}(\overline{F}_{e,2}^{(6)})$  are mainly excited in oblique 13 incoming waves. For kh < 3.8,  $\overline{F}_{e,1}^{(6)}$  and  $\overline{F}_{e,2}^{(6)}$  for  $\beta = \pi/4$  are both larger than the other cases with 14 different value of  $\beta$ .

Fig. 6. Normalised wave excitation forces acting on the two caissons vs. *kh* for five incident wave angles:  $\beta = 0$ ,  $\pi/6$ ,  $\pi/4$ ,  $\pi/3$  and  $\pi/2$  with e/h=1.0: (a)  $\overline{F}_{e,1}^{(1)}$ ; (b)  $\overline{F}_{e,2}^{(1)}$ ; (c)  $\overline{F}_{e,1}^{(2)}$ ; (d)  $\overline{F}_{e,2}^{(2)}$ ; (e)  $\overline{F}_{e,1}^{(3)}$ ; (f)  $\overline{F}_{e,2}^{(3)}$ .

Fig. 7. Normalised wave excitation moments acting on the two caissons vs *kh* for five incident wave angles  $\beta = 0$ ,  $\pi/6$ ,  $\pi/4$ ,  $\pi/3$  and  $\pi/2$  with e/h=1.0: (a)  $\overline{F}_{e,1}^{(4)}$ ; (b)  $\overline{F}_{e,2}^{(4)}$ ; (c)  $\overline{F}_{e,1}^{(5)}$ ; (d)  $\overline{F}_{e,2}^{(5)}$ ; (e)  $\overline{F}_{e,1}^{(6)}$ ; (f)  $\overline{F}_{e,2}^{(6)}$ .

# 5 6.2 Effect of spacing between caissons

To study the influence of the spacing between the caissons, e, we consider the same two
caissons deployed with four different spacings, i.e., e/h=0.5, 1.0, 1.5 and 2.0, suffering from
incoming waves with β=π/6 are studied. In addition, as a comparison, wave diffraction from an
individual caisson isolated in open sea is also analytically solved by using the method of [25]. The
isolated caisson case is equivalent to the two-caisson case with an extremely large spacing
between them, i.e., e/h=∞, that the hydrodynamic interaction is vanishing. For such case, *F*<sup>(i)</sup><sub>e,1</sub> = *F*<sup>(i)</sup><sub>e,2</sub>, *i*=1,2,...,6.

1 Figures 8 and 9 illustrate the results of excitation forces and moments acting on the caissons, respectively. As shown in Fig. 8a, when the two caissons are placed far away from each other, i.e., 2 the isolated caisson case, the  $\overline{F}_{e,1}^{(1)}(\overline{F}_{e,2}^{(1)})$ -kh is a one peak curve. While when they are arranged 3 close to each other, e.g.,  $e/h = 0.5 \sim 2.0$ , affected by the reflected waves from Caisson 2, frequency 4 response of the surge excitation force acting on Caisson 1, i.e.,  $\overline{F}_{e,1}^{(1)}$ , is found to oscillate around 5 the  $\overline{F}_{e,1}^{(1)}$ -*kh* curve of isolated caisson case. It means that for different wave conditions,  $\overline{F}_{e,1}^{(1)}$  can 6 be either strengthened or weakened by the hydrodynamic interaction between the caissons. As e/h7 turns larger, strengthening and weakening effects of the hydrodynamic interaction on  $\bar{F}_{e,1}^{(1)}$  can 8 switch for a smaller change of kh. Different from  $\overline{F}_{e,1}^{(1)}$ , thanks to the sheltering effect of Caisson 9 1,  $\overline{F}_{e,2}^{(1)}$  is found weakened by hydrodynamic interaction for most wave conditions within  $kh < \infty$ 10 11

5.0 (Fig. 8b). For 3.0 < kh < 5.0,  $\overline{F}_{e,1}^{(1)}$  with e/h=0.5 is obviously smaller than the other cases. As kh increases from 0 to 2.5,  $\overline{F}_{e,1}^{(2)}$  increases from 0 to 0.11 and there is nearly no influence of e on  $\overline{F}_{e,1}^{(2)}$  for these wave frequencies (Fig. 8c). As kh keeps increasing from 2.5 toward 5.0,  $\overline{F}_{e,1}^{(2)}$  for the isolated caisson case stays at a flat level of  $\overline{F}_{e,1}^{(2)} = 1.1$ . Whereas for the two caissons close to each other, fluctuations of the  $\overline{F}_{e,1}^{(2)}$ -kh curve around that of the isolated caisson case are observed. The smaller the e/h, the stronger fluctuations occur. These fluctuations are not found for the sway excitation force acting on Caisson 2 (Fig. 8b). It should be noted that for kh < 4.0, although Caisson 2 is located at the lee side of Caisson 1,  $\overline{F}_{e,2}^{(2)}$  is strengthened by the hydrodynamic interaction. The smaller the e/h, the larger  $\overline{F}_{e,1}^{(2)}$  is obtained. Similar to the effect of e on  $\overline{F}_{e,1}^{(1)}$ , the  $\overline{F}_{e,1}^{(3)}$ -kh curves representing two-caisson cases are also

Similar to the effect of e on  $F_{e,1}^{(1)}$ , the  $F_{e,1}^{(3)}$ -kh curves representing two-caisson cases are also observed to oscillate around the curve of isolated caisson case (Fig.8e). As e/h turns larger, strengthening and weakening effects of the hydrodynamic interaction on  $\overline{F}_{e,1}^{(3)}$  switch more frequently for the same range of kh. It should be noted that generally the hydrodynamic interaction has opposite effects on  $\overline{F}_{e,1}^{(1)}$  and  $\overline{F}_{e,1}^{(3)}$ , e.g., for the case with e/h =1.5 at kh =3.0,  $\overline{F}_{e,1}^{(1)}$  is strengthened whereas  $\overline{F}_{e,1}^{(3)}$  is weakened. The heave excitation force acting on Caisson 2, i.e.,  $\overline{F}_{e,2}^{(3)}$  (Fig. 8f) is affected by e in a similar way as  $\overline{F}_{e,2}^{(1)}$  is influenced (Fig. 8b).

has opposite effects on  $F_{e,1}^{(4)}$  and  $F_{e,1}^{(4)}$ , e.g., for the case with e/h = 1.5 at kh = 5.0,  $F_{e,1}^{(4)}$  is strengthened whereas  $\overline{F}_{e,1}^{(3)}$  is weakened. The heave excitation force acting on Caisson 2, i.e.,  $\overline{F}_{e,2}^{(3)}$  (Fig. 8f) is affected by e in a similar way as  $\overline{F}_{e,2}^{(1)}$  is influenced (Fig. 8b). Both  $\overline{F}_{e,1}^{(4)}$  and  $\overline{F}_{e,2}^{(4)}$  vanish around kh = 3.4, regardless of the value of e/h (Figs.9a and 9b). For kh < 3.4,  $\overline{F}_{e,1}^{(4)}$  is not affected by e, neither. Influence of e on  $\overline{F}_{e,1}^{(4)}$  mainly happens at 4.0 kh < 5.0, where  $\overline{F}_{e,1}^{(4)}$  in the case with e/h = 0.5 is larger than those for the other cases. The results as given in Fig.9b show that  $\overline{F}_{e,2}^{(4)}$  is approximately not influenced by e unless e is rather small, e.g., e/h = 0.5, for which a slightly larger  $\overline{F}_{e,2}^{(4)}$  is obtained for kh < 3.4, whereas an obvious smaller  $\overline{F}_{e,2}^{(4)}$  is obtained for kh > 3.5.

smaller  $\overline{F}_{e,2}^{(4)}$  is obtained for kh > 3.5. Effect of e on  $\overline{F}_{e,1}^{(5)}$  and  $\overline{F}_{e,2}^{(5)}$  (Figs.9c and 9d) is rather similar to that on  $\overline{F}_{e,1}^{(1)}$  and  $\overline{F}_{e,2}^{(1)}$ (Figs. 8a and 8b). Hence the description is not repeated here. The yaw moments acting on each caisson, especially those on Caisson 1, are found sensitive to e for kh > 2.5 (Figs.9e and 9f).

Fig. 8. Normalised wave excitation forces acting on the two caissons vs *kh* for four spacing *e/h*=0.5, 1.0, 1.5 and 2.0, together with the isolated case with  $\beta = \pi/6$ : (a)  $\overline{F}_{e,1}^{(1)}$ ; (b)  $\overline{F}_{e,2}^{(1)}$ ; (c)  $\overline{F}_{e,1}^{(2)}$ ; (d)  $\overline{F}_{e,2}^{(2)}$ ; (e)  $\overline{F}_{e,1}^{(3)}$ ; (f)  $\overline{F}_{e,2}^{(3)}$ .

> 4 5

Fig. 9. Normalised wave excitation moments acting on the two caissons vs. *kh* for four spacings, e/h=0.5, 1.0, 1.5 and 2.0, together with the isolated case with  $\beta = \pi/6$ : (a)  $\overline{F}_{e,1}^{(4)}$ ; (b)  $\overline{F}_{e,2}^{(4)}$ ; (c)  $\overline{F}_{e,1}^{(5)}$ ; (d)  $\overline{F}_{e,2}^{(5)}$ ; (e)  $\overline{F}_{e,1}^{(6)}$ ; (f)  $\overline{F}_{e,2}^{(6)}$ .

6 6.3 Effect of layout

7 In practice, different configurations of the caissons, e.g., side by side and staggered, will be
8 encountered during the transport and installation process. In this subsection, the layout with the
9 two caissons in parallel at the same distance from their centers is considered. As shown in Fig. 10,
10 the only variable parameter in the different configurations is the angle of the line connecting the
11 caisson centers with the *x*-axis, which is defined as the configuration angle *α*.

Fig. 10. Definition of the configuration angle  $\alpha$ .

The two caissons with α =0, π/6, π/4, π/3 and π/2 subjected to incident waves with β=π/6 are
analytically studied. Figures 11 and 12 present the comparison of the results of wave excitation
forces and moments, respectively.

1 2

3

7 As  $\alpha$  increases from 0 to  $\pi/2$ , the  $\overline{F}_{e,1}^{(1)}$ -kh curve changes from double-peaked curve into 8 single-peaked one (Fig.11a). With the increase of  $\alpha$ ,  $\overline{F}_{e,1}^{(1)}$  at kh = 2.0 and 4.1 turn smaller and 9 smaller, whereas  $\overline{F}_{e,1}^{(1)}$  at kh=3 gets larger and larger, revealing that opposite effects of  $\alpha$  on  $\overline{F}_{e,1}^{(1)}$ 10 might happen for different wave conditions. While for all the wave conditions examined, except 11 few wave frequencies around kh=4.0, a larger  $\alpha$  generally results in a larger  $\overline{F}_{e,2}^{(1)}$  (Fig.11b).

In the five cases with  $\alpha$  increasing from 0 to  $\pi/2$ , the value of  $\overline{F}_{e,1}^{(2)}$  could change a lot for some specified wave conditions (Fig.11c). Take kh=2.6 as an example,  $\overline{F}_{e,1}^{(2)}$  for  $\alpha=\pi/4$  is only 0.082, whereas for  $\alpha=\pi/2$ ,  $\overline{F}_{e,1}^{(2)}$  reaches 0.154, which is approximately two times as large as that when  $\alpha=\pi/4$ . Similar significant difference of  $\overline{F}_{e,2}^{(2)}$  induced by variation of  $\alpha$  can be observed for most wave conditions within 2.0<kh<5.0 (Fig.11d). Among the five cases with different values of  $\alpha$ , the cases with  $\alpha=\pi/2$  and  $\pi/3$  give the maximum and minimum values of  $\overline{F}_{e,2}^{(2)}$ , respectively, for most wave conditions. For kh ranging from 3.0 to 5.0, the maximum value of  $\overline{F}_{e,2}^{(2)}$  is always two times as large as that of the minimum approximately.

For 1.2<*kh*<2.1,  $\overline{F}_{e,1}^{(3)}$  with  $\alpha = \pi/2$  is the largest among the result in the five cases (Fig.11e). While for 2.4< *kh*<3.5, on the contrary,  $\overline{F}_{e,1}^{(3)}$  with  $\alpha = \pi/2$  turns to be the smallest one. As a comparison,  $\overline{F}_{e,2}^{(3)}$  is maximized and minimized when  $\alpha = \pi/2$  and  $\alpha = 0$ , respectively, for any wave conditions at 1.9<*kh*<5.0 (Fig.11f).

For 1.0<*kh*<1.7,  $\overline{F}_{e,1}^{(4)}$  with  $\alpha = \pi/2$  is much smaller than any of the other four cases, whereas for *kh*>2.2,  $\overline{F}_{e,1}^{(4)}$  of such case turns to be the largest one (Fig.12a). Whatever the value of  $\alpha$  is, a minimum value of  $\overline{F}_{e,1}^{(4)}$  occurs around *kh*=3.3. While the *kh* corresponding to the minimum value of  $\overline{F}_{e,2}^{(4)}$  is a bit more sensitive to the variation of  $\alpha$ , e.g., the *kh* corresponding to the minimum of  $\overline{F}_{e,2}^{(4)}$  for  $\alpha = \pi/3$  and  $\pi/2$  are 3.0 and 3.6, respectively. For *kh* ranging from 1.3 to 3.1,  $\overline{F}_{e,2}^{(4)}$  for the cases with  $\alpha = \pi/3$  and  $\pi/2$  are always the smallest and largest ones, respectively, among the five cases.

31 The frequency response curves of  $\overline{F}_{e,1}^{(5)}$  and  $\overline{F}_{e,2}^{(5)}$  for different  $\alpha$  (Figs. 12c and 12d) are

found to be similar to those of  $\overline{F}_{e,1}^{(1)}$  and  $\overline{F}_{e,2}^{(1)}$  in Figs. 11a and 11b. The discussion of the effect of  $\alpha$  on  $\overline{F}_{e,1}^{(1)}$  and  $\overline{F}_{e,2}^{(1)}$  can be applied to  $\overline{F}_{e,1}^{(5)}$  and  $\overline{F}_{e,2}^{(5)}$  as well. Figures 12e and 12f illustrate the results of  $\overline{F}_{e,1}^{(6)}$  and  $\overline{F}_{e,2}^{(6)}$ . For kh>2.5, compared with the other four cases,  $\overline{F}_{e,2}^{(6)}$  with  $\alpha=0$  is much larger and deserves more attention for stability. 

Fig. 11. Normalised wave excitation forces acting on the two caissons vs kh for different configuration angle  $\alpha = 0, \pi/6, \pi/4, \pi/3$  and  $\pi/2$  with  $\beta = \pi/6$ : (a)  $\overline{F}_{e,1}^{(1)}$ ; (b)  $\overline{F}_{e,2}^{(1)}$ ; (c)  $\overline{F}_{e,1}^{(2)}$ ; (d)  $\overline{F}_{e,2}^{(2)}$ ; (e)  $\overline{F}_{e,1}^{(3)}$ ; (f)  $\overline{F}_{e,2}^{(3)}$ .

Normalised wave excitation moments acting on the two caissons vs *kh* for different configuration angle  $\alpha = 0$ ,  $\pi/6$ ,  $\pi/4$ ,  $\pi/3$  and  $\pi/2$  with  $\beta = \pi/6$ : (a)  $\overline{F}_{e,1}^{(4)}$ ; (b)  $\overline{F}_{e,2}^{(4)}$ ; (c)  $\overline{F}_{e,1}^{(5)}$ ; (d)  $\overline{F}_{e,2}^{(5)}$ ; (e)  $\overline{F}_{e,1}^{(6)}$ ; (f)  $\overline{F}_{e,2}^{(6)}$ .

6 To examine the effect of the shape of the cross section of the cylinders, we consider two 7 identical caissons with a similar deployment to Fig. 2, and with the same horizontal distance 8 between the centroids of 30 m, but with different cross sections. More specifically, four cross 9 sections are examined (Fig. 13a; only one caisson is plotted), in which  $\kappa$  and  $\kappa'$  represent the ratios 10 of the lengths of the two straight edge sections relative to the corner radius,  $R_0$  (Fig. 13b). All 11 these cross sections have the same area. Note  $\kappa'$  is set to zero unless otherwise specified. As  $\kappa$ 

- 1 increases from 0, the cross section evolves from circular into quasi-elliptical with its major axis in
- 2 parallel with the y-axis. The larger the  $\kappa$ , the slenderer the shape. The exact size of the cross
- section for the case  $\kappa=2$  can be found in Fig. 2. For  $\kappa=\kappa'=2$ , the cross section turns into a square
- 4 with circular corners. The caisson draft of all these four cases  $d_n=5$  m, water depth h=20 m, and
- 5 incident wave direction  $\beta = \pi/6$ .

8

Fig. 13. (left) Schematic of the four shapes of cross section; (right) Definition of  $\kappa$  and  $\kappa'$ .

9 Figure 14 shows the variation with *kh* of the excitation forces acting on each caisson in surge,
10 sway and heave modes for different shapes of cross section. Results of the excitation moments
11 acting on each caisson in roll, pitch and yaw modes are given in Fig. 15.

12 Since the caissons in the case  $\kappa=2$  are the slenderest among the four cases, the wave excitation forces/moments acting on each caisson in this case in surge, pitch and yaw modes are 13 14 the largest among the case studies for the majority of the wave frequencies tested, and the wave excitation forces in the sway mode are the smallest. Similar curves representing the surge and 15 heave wave excitation forces, together with the pitch excitation moment acting on each caisson for 16 cases  $\kappa=0$  and  $\kappa=\kappa'=2$  are observed (Figs. 14a, 14b, 14e, 14f, 15c and 15d). Although the length of 17 the caissons in the case  $\kappa = \kappa' = 2$  along the x-axis is smaller than the case  $\kappa = 0$ ,  $\overline{F}_{e,1}^{(2)}$  and  $\overline{F}_{e,2}^{(2)}$  for 18 case  $\kappa = \kappa' = 2$  are the largest for all the wave frequencies tested (Figs.14 c and 14d). In long waves, 19 20 e.g., kh < 2.0, the wave excitation forces acting on each caisson in heave mode are nearly independent of the shape of the cross sections with the same area (Figs. 14e and 14f). For 21 22

22 2.0<kh<3.8 a larger  $\overline{F}_{e,1}^{(3)}$  can be obtained for the case with a larger  $\kappa$  and  $\kappa'=0$ . 23 As shown in Figs.15a and 15b,  $\overline{F}_{e,1}^{(4)}$  and  $\overline{F}_{e,2}^{(4)}$  for cases  $\kappa=1$  and 2 vanish for certain wave 24 conditions. As a comparison,  $\overline{F}_{e,1}^{(4)}$  and  $\overline{F}_{e,2}^{(4)}$  for cases  $\kappa=0$  and  $\kappa=\kappa'=2$  never vanish for the 25 entire range of wave frequencies tested. Moreover,  $\overline{F}_{e,1}^{(4)}$  and  $\overline{F}_{e,2}^{(4)}$  for case  $\kappa=\kappa'=2$  are larger 26 compared to case  $\kappa=0$  for the whole range of computed wave conditions. As expected, the yaw 27 excitation moments vanish for circular caissons, i.e., case  $\kappa=0$  (Fig. 15e and 15f).

Fig. 14. Normalised wave excitation forces acting on the two caissons vs. *kh* for four shapes of cross section: (a)  $\overline{F}_{e,1}^{(1)}$ ; (b)  $\overline{F}_{e,2}^{(1)}$ ; (c)  $\overline{F}_{e,1}^{(2)}$ ; (d)  $\overline{F}_{e,2}^{(2)}$ ; (e)  $\overline{F}_{e,1}^{(3)}$ ; (f)  $\overline{F}_{e,2}^{(3)}$ .

# 4 7 Conclusions

5 In this paper we developed an analytic model for the problem of wave diffraction from multiple truncated cylinders with arbitrary cross sections. Assuming the cylinders are subjected to 6 7 regular waves of small steepness, linear potential flow theory is applied in the analytic model. The whole water domain is divided into interior regions below each cylinder and an exterior region 8 9 representing the rest of the water domain. On this basis, the diffracted spatial velocity potential in 10 these regions can be written as series of eigen-functions. The Fourier series method combined 11 with the eigen-function expansion matching method are then used to satisfy the wetted surface 12 body conditions and continuity conditions between adjacent regions, and to determine the 13 unknown coefficients of the expressions of the diffracted spatial potential. Excellent agreement is 14 found between the analytic results of wave excitations forces and moments and the numerical 15 results obtained from a BEM-based code and the published data as well, which validates the 16 analytic model. The model is then applied to study wave diffraction from two caissons and to

explore the effect of the incident wave angle, spacing between two caissons and configuration
angle on the wave excitation forces and moments. Wave diffraction from the two identical
caissons with some other shapes of cross section are also examined. The following conclusions
may be drawn.

For two parallel caissons with the same dimensions located in a row, when incident waves propagate along the channel between them, i.e.,  $\beta = \pi/2$ , the surge excitation force, pitch and yaw excitation moments acting on each caisson are triggered by the hydrodynamic interaction between the caissons. For different wave frequencies, changing the incident wave angle might play opposite roles, i.e., strengthening and weakening roles, on  $\overline{F}_{e,1}^{(3)}$ . For kh < 3.8, the yaw excitation moments on both caissons for  $\beta = \pi/4$  are larger than in the other cases (with different values of  $\beta$ ).

Frequency responses of the surge, sway and heave excitation forces and also the pitch and yaw moments acting on Caisson 1 are found to oscillate around the  $\overline{F}_{e,1}^{(i)}$ -kh curve of isolated caisson case. This can be explained by the strengthening and weakening effects of the hydrodynamic interaction. As the spacing between the caissons increases, strengthening and weakening effects alternate at smaller intervals of kh.

16 As  $\alpha$  increases from 0 to  $\pi/2$  with  $\beta = \pi/6$ , the  $\overline{F}_{e,1}^{(1)}$ -*kh* and  $\overline{F}_{e,1}^{(5)}$ -*kh* curves change from 17 double-peaked curves into single-peaked ones. With the increase of  $\alpha$ , opposite effects of  $\alpha$  on 18  $\overline{F}_{e,1}^{(1)}$  and  $\overline{F}_{e,1}^{(5)}$  might happen for different wave conditions. For most wave conditions, the cases 19 with  $\alpha = \pi/2$  and  $\pi/3$  give the maximum and minimum values of  $\overline{F}_{e,2}^{(2)}$  among the cases with five 20 different value of  $\alpha$ , respectively. The maximum value of  $\overline{F}_{e,2}^{(2)}$  can be twice as large as that of 21 the minimum for *kh*> 3.0. Whatever the value of  $\alpha$  is, a minimum value of  $\overline{F}_{e,1}^{(4)}$  occurs around 22 *kh*=3.3. For *kh* ranging from 1.3 to 3.1,  $\overline{F}_{e,2}^{(4)}$  is always the minimum and maximum for  $\alpha = \pi/3$ 23 and  $\pi/2$ , respectively, among the five cases. For short waves, e.g., *kh*>2.5,  $\overline{F}_{e,2}^{(6)}$  with  $\alpha = 0$  is 24 much larger than in the other four cases, and it deserves more attention for stability.

The wave excitation forces/moments acting on each caisson in case  $\kappa=2$  in surge, pitch and yaw modes are the largest among the case studies for the majority of the wave frequencies tested, and the wave excitation forces in the sway mode are the smallest.  $\overline{F}_{e,1}^{(2)}$  and  $\overline{F}_{e,2}^{(2)}$  for case  $\kappa=\kappa'=2$  are the largest for the entire range of wave frequencies tested.

The research presented in this paper focused on wave diffraction from multiple stationary truncated cylinders. The analytic model established in this paper, together with that developed by Zheng, Zhang, Liu and Iglesias [41] for solving the problem of wave radiation from cylinders oscillating independently in the absence of an incident wave, can be used to calculate the hydrodynamic response of an array of truncated cylinders of arbitrary cross sections freely floating in water waves.
